Do community health workers improve the care of people with hypertension?

Community health workers (CHWs), carry out functions related to healthcare delivery, have no formal professional designation to deliver healthcare, but are trained as part of an intervention, and have a relationship with the community being served. They can be used to facilitate improvement in the management of chronic conditions like hypertension.

Key messages

In people with hypertension:

- CHWs probably improve behavioural changes (such as appointment keeping and adherence to medication), blood pressure control, and the 5-year mortality rate.

- CHWs may slightly improve healthcare utilization and health systems outcomes (such as reduced hospital admissions).

- All the included studies were conducted in a high-income country but mainly in poor communities.
Background

Hypertension is a significant public health problem. Only about 30% of people who are diagnosed with hypertension have their blood pressure under control. In poor settings, overcoming barriers such as health beliefs and values, insufficient access to culturally sensitive care, lack of knowledge about hypertension, and an absence of self-management skills are key to effective hypertension control. In order to improve health outcomes in the community, the involvement of trained laypeople, known as community health workers (CHWs), can have an important role. CHWs can be used to facilitate access to care, promote continuity of care, facilitate the adoption of self-care skills, and enhance compliance with treatment regimens.

About the systematic review underlying this summary

Review objective: To examine the effectiveness of CHWs in supporting the care of people with hypertension

Date of most recent search: May 2006

Limitations: This is a well-conducted systematic review with only minor limitations.

Summary of findings

Fourteen studies involving 61,366 participants (median of 180 participants per CHW) were included in this systematic review.

1) Health outcomes

Of the ten studies that examined the effects of CHWs on blood pressure control, nine reported positive improvements. One study reported mortality reductions and two showed improvements in other patient outcomes, such as changes in heart mass and cardiovascular risk.

➔ CHWs probably improve blood pressure control. The certainty of this evidence is moderate.

➔ CHWs probably improve the 5-year mortality rate. The certainty of this evidence is moderate.

p: p-value  GRADE: GRADE Working Group grades of evidence (see above and last page)

About the certainty of the evidence (GRADE) *

High: This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different† is low.

Moderate: This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different† is moderate.

Low: This research provides some indication of the likely effect. However, the likelihood that it will be substantially different† is high.

Very low: This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different† is very high.

* This is sometimes referred to as ‘quality of evidence’ or ‘confidence in the estimate’.
† Substantially different = a large enough difference that it might affect a decision.

See last page for more information.
2) Behavioral changes

Positive behavioral changes were noted in nine of the ten studies measuring such changes. Two studies that addressed patient satisfaction found that the competency of the CHWs and the social support they provided were very important to the participants.

➔ CHWs probably improve behavioural changes such as appointment keeping and adherence to medication. The certainty of this evidence is moderate.

3) Healthcare system outcomes

Four studies reported improvements in healthcare utilization and systems outcomes, including more appropriate use of the emergency department, reduced admissions to the hospital through the emergency room, cost savings, a larger proportion of participants having a physician or nurse for hypertension care, a higher number of appropriate follow-up visits, greater responsiveness of providers to patients’ needs, and increased participation of CHWs in planning meetings.

➔ CHWs may slightly improve healthcare utilization and systems outcomes. The certainty of this evidence is low.
### Relevance of the review for low-income countries

#### Findings

**APPLICABILITY**

- All studies were conducted in high-income countries but most of them were directed to poor and vulnerable populations.
- Generally high level of organisation and support provided by the health systems.

**EQUITY**

- Overall, the included studies provided little data regarding differential effects of the interventions for disadvantaged populations.

**ECONOMIC CONSIDERATIONS**

- There is little information regarding the cost-effectiveness of CHWs but one study reported cost savings.

**MONITORING & EVALUATION**

- None of the studies were conducted in a low-income country.
- There were considerable differences in numbers, and training of CHWs.

#### Interpretation*

**APPLICABILITY**

- Factors that should be considered about the applicability in low-income countries include:
  - The availability of routine data of recipients of the intervention
  - The financial and organisational resources to provide clinical and managerial support for CHWs
  - The supplies necessary for CHWs to deliver services
  - Additional services stimulated by widespread programme implementation
  - The integration of CHWs into the primary healthcare team and the capacity of other health professionals to collaborate with them are also key factors of a successful CHW intervention.

**EQUITY**

- Many CHWs programmes aim to address inequity by extending services to underserved communities. Community involvement in programme decisions, such as selection of CHWs, may improve their acceptability and success.
  - Some interventions used systems (e.g. telephone, registers, and reminders) that might exclude the most disadvantaged, thus worsening inequities.

**ECONOMIC CONSIDERATIONS**

- The cost of CHW programmes is likely to be highly variable and must be estimated based on specific local conditions outside research settings.
  - Before CHW programmes are scaled up, robust evidence is needed regarding the cost-effectiveness of the interventions delivered by CHWs.

**MONITORING & EVALUATION**

- If decision makers from low-income countries choose to implement CHW programmes for managing hypertension, they should ensure that these programmes include robust evaluation including health outcomes and cost-effectiveness.
  - The acceptability of CHW programmes by recipients and health professionals may need to be evaluated before such programmes are taken to scale.

*Judgements made by the authors of this summary, not necessarily those of the review authors, based on the findings of the review and consultation with researchers and policymakers in low-income countries. For additional details about how these judgements were made see: [www.supportsummaries.org/methods](http://www.supportsummaries.org/methods).

About certainty of the evidence (GRADE)
The “certainty of the evidence” is an assessment of how good an indication the research provides of the likely effect; i.e. the likelihood that the effect will be substantially different from what the research found. By “substantially different” we mean a large enough difference that it might affect a decision. These judgements are made using the GRADE system, and are provided for each outcome. The judgements are based on the study design (randomised trials versus observational studies), factors that reduce the certainty (risk of bias, inconsistency, indirectness, imprecision, and publication bias) and factors that increase the certainty (a large effect, a dose response relationship, and plausible confounding). For each outcome, the certainty of the evidence is rated as high, moderate, low or very low using the definitions on page 3.
