Does additional social support during at-risk pregnancy improve perinatal outcomes?

Additional social support has been advocated for socially disadvantaged pregnant women because they are at greater risk of experiencing adverse birth outcomes. Support may include advice and counselling (e.g. about nutrition, rest, stress management, or the use of alcohol), tangible assistance (e.g. transportation to clinic appointments, or household help), and emotional support (e.g. reassurance, or sympathetic listening). The additional social support may be delivered by multidisciplinary teams of healthcare workers or lay health workers during home visits, clinic appointments or by telephone.

Key messages

- Compared to usual care, providing additional social support during an at-risk pregnancy probably leads to fewer caesarean births and may lead to fewer antenatal hospital admissions.

- Compared to usual care, providing additional social support during an at-risk pregnancy probably has little or no effect on the incidence of low birth weight, preterm births, or perinatal deaths.

- The studies included in this review were conducted among socially disadvantaged groups in middle- and high-income countries. Disadvantaged groups in some high- and middle-income countries may share similar characteristics to disadvantaged groups in low-income countries, and the results of these studies may therefore be transferable to low-income country settings.
Background

Health problems associated with low birth weight (<2,500 grams) consume a significant proportion of healthcare resources. In low-income countries, chronic maternal malnutrition and preterm births are major causes of low birth weight.

This summary is based on a review which assessed the effects of additional social support during pregnancy for women at increased risk of low birth weight babies, compared to usual care. The authors included studies if the additional support was provided during the pregnancy and continued until the birth of the baby, or was provided into the postnatal period.

About the systematic review underlying this summary

Review objective: To assess the effects of programmes offering additional social support compared with routine care for pregnant women who are believed to be at high risk for giving birth to babies that are either preterm or weigh less than 2,500 grams, or both, at birth.

Limitations: This is a well-conducted systematic review with only minor limitations.

Summary of findings

The review identified 17 trials with a total study population of 12,264 women. Support was provided by midwives or nurses (11 studies), social workers (4), a multidisciplinary team of nurses, psychologists, midwives, or by trained lay health workers (2 studies).

- Additional social support during at-risk pregnancy, compared to usual care, probably leads to little or no difference in the incidence of low birth weight, preterm births, stillbirths, or neonatal deaths. The certainty of this evidence is moderate.

- Additional social support during at-risk pregnancy, compared to usual care, probably leads to fewer Caesarean sections. The certainty of this evidence is moderate.

- Additional social support during at-risk pregnancy, compared to usual care, may lead to fewer antenatal hospital admissions. The certainty of this evidence is low.

About the certainty of the evidence (GRADE) *

High: This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different† is low.

Moderate: This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different† is moderate.

Low: This research provides some indication of the likely effect. However, the likelihood that it will be substantially different† is high.

Very low: This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different† is very high.

* This is sometimes referred to as ‘quality of evidence’ or ‘confidence in the estimate’.
† Substantially different = a large enough difference that it might affect a decision

See last page for more information.
## Additional social support versus usual care during at-risk pregnancy

**Difference:**

- **Low birth weight:** 11 fewer births <2500 gram per 1000 births (Margin of error: 22 fewer cases to 4 more)
- **Preterm births:** 11 fewer births <37 weeks per 1000 births (Margin of error: 23 fewer cases to 1 more)
- **Perinatal deaths:** 1 fewer death per 1000 births (Margin of error: 7 fewer cases to 7 more)
- **Caesarean births:** 29 fewer caesarean births per 1000 births (Margin of error: 7 to 50 fewer cases)
- **Antenatal hospital admissions:** 113 fewer antenatal hospital admissions per 1000 births (Margin of error: 43 to 172 fewer cases)

---

*The risk WITHOUT the intervention is based on usual care. The corresponding risk WITH the intervention (and the 95% confidence interval for the difference) is based on the overall relative effect (and its 95% confidence interval).*
# Relevance of the review for low-income countries

## Findings vs Interpretation*

### APPLICABILITY

- The studies were from a wide range of settings. Socially disadvantaged groups in both high-income and middle-income countries were included.

  - Disadvantaged groups in some high- and middle-income countries may share common characteristics with disadvantaged groups in low-income countries. The findings may therefore be transferable to low-income country settings.

### EQUITY

- The studies were focused on socio-economically vulnerable groups, including people with low levels of income and education.

  - The challenges faced by socio-economically vulnerable women in low-income countries can be complex and extensive. This might limit the potential for them to benefit from additional social support, if these challenges are not addressed. Such women may, for example, need to travel long distances to access healthcare facilities. When they arrive, staff shortages (especially in rural areas) may impact on the quality of care they receive. Many vulnerable women may choose not to attend facility-based antenatal care and may deliver their children in their own homes instead.

  - Human resource levels in low-income settings, especially in rural areas, may be limited. This might also limit the potential for them to benefit from additional social support, if such shortages are not addressed.

- Social support was mostly provided by appropriately trained professional healthcare workers.

### ECONOMIC CONSIDERATIONS

- Most of the study interventions were facility-based and performed by professional healthcare workers.

  - Professional healthcare workers in many low-income countries are often overstretched and the introduction of facility-based interventions may not be feasible or may require additional health workers. The cost of providing additional health professionals or trained lay health workers is likely to be highly variable. An estimate of such costs must be based on an understanding of specific local settings and conditions.

- Social support in a small number of studies was delivered by trained lay health workers.

### MONITORING & EVALUATION

- This review showed that additional social support results in little or no difference in important perinatal outcomes.

  - Any decision to implement additional social support programmes should identify what changes in outcomes the programme is intended to achieve and a plan for monitoring those outcomes and evaluating the impact of the programme on those outcomes.

*Judgements made by the authors of this summary, not necessarily those of the review authors, based on the findings of the review and consultation with researchers and policymakers in low-income countries. About certainty of the evidence (GRADE)
The "certainty of the evidence" is an assessment of how good an indication the research provides of the likely effect; i.e. the likelihood that the effect will be substantially different from what the research found. By “substantially different” we mean a large enough difference that it might affect a decision. These judgements are made using the GRADE system, and are provided for each outcome. The judgements are based on the study design (randomised trials versus observational studies), factors that reduce the certainty (risk of bias, inconsistency, indirectness, imprecision, and publication bias) and factors that increase the certainty (a large effect, a dose response relationship, and plausible confounding). For each outcome, the certainty of the evidence is rated as high, moderate, low or very low using the definitions on page 3.
