What are the effects of behavioral interventions to improve adherence to antiretroviral therapy?

Adherence can be defined as the extent to which patients follow the instructions they are given for prescribed treatments. Highly active antiretroviral therapy (HAART) has demonstrated remarkable success in reducing morbidity, mortality, and healthcare costs for HIV-positive people. The lifesaving benefits of HAART are not achieved if patients do not take them as prescribed. Behavioral interventions are intended to assist patients with this task.

Key messages

➤ Behavioral interventions probably lead to slightly better adherence to HAART.

➤ Behavioral interventions may slightly improve the number of patients with undetectable viral load (a laboratory measure of successful HAART).

➤ No studies measuring patient outcomes such as morbidity and mortality were identified.

➤ Only one included study was conducted in a low-income country.
Background

Highly active antiretroviral therapy (HAART) has demonstrated remarkable success in inhibiting HIV viral replication and reducing morbidity, mortality, and overall healthcare costs for HIV-positive people. Without strict attention to dosing schedules and dietary restrictions, the effectiveness of HAART is severely compromised. Non-adherence to HAART is very common. Potential causes include problems with the regimen (e.g. adverse effects), poor instructions, poor provider-patient relationships, poor memory, and patients’ disagreement with the need for treatment or inability to pay for it. Given the multifaceted dimensions of this phenomenon, there is a wide array of possible interventions. Behavioral interventions represent a key strategy for addressing non-adherence to HAART.

How this summary was prepared

After searching widely for systematic reviews that can help inform decisions about health systems, we have selected ones that provide information that is relevant to low-income countries. The methods used to assess the reliability of the review and to make judgements about its relevance are described here: www.supportsummaries.org/how-support-summaries-are-prepared/

Knowing what’s not known is important

A reliable review might not find any studies from low-income countries or might not find any well-designed studies. Although that is disappointing, it is important to know what is not known as well as what is known.

A lack of evidence does not mean a lack of effects. It means the effects are uncertain. When there is a lack of evidence, consideration should be given to monitoring and evaluating the effects of the intervention, if it is used.
**About the systematic review underlying this summary**

**Review objective:** To summarise literature on the effects of patient support strategies and education for improving adherence to highly active antiretroviral therapy (HAART) in people living with HIV/AIDS.

Summary of findings

This review found 19 studies conducted in high-income countries, mostly in primary care HIV clinics. Studies evaluated behavioral interventions consisting of one or more of the following components: didactic information, interactive discussion, behavioral therapy, and reminders.

- Behavioral interventions probably lead to slightly better adherence to HAART. The certainty of this evidence is moderate.
- Behavioral interventions may slightly improve the number of patients with undetectable viral load. The certainty of this evidence is low.
- No studies measuring patient outcomes such as morbidity and mortality were identified.

About the certainty of the evidence (GRADE) *

- **High**: This research provides a very good indication of the likely effect. The likelihood that the effect will be substantially different† is low.
- **Moderate**: This research provides a good indication of the likely effect. The likelihood that the effect will be substantially different† is moderate.
- **Low**: This research provides some indication of the likely effect. However, the likelihood that it will be substantially different† is high.
- **Very low**: This research does not provide a reliable indication of the likely effect. The likelihood that the effect will be substantially different† is very high.

* This is sometimes referred to as ‘quality of evidence’ or ‘confidence in the estimate’.
† Substantially different = a large enough difference that it might affect a decision

## Relevance of the review for low-income countries

<tbody>
<tr>
<td><strong>APPLICABILITY</strong></td>
<td></td>
</tr>
<tr>
<td>➤ All studies were conducted in high-income countries. The update of the review includes 3 studies in Brazil, China, and Mozambique, with mixed results.</td>
<td>➤ There are several ways in which the effects of interventions to improve adherence in high-income countries and low-income countries might differ, for instance cultural differences or availability of technologies. ➤ In some regions, especially in sub-Saharan Africa, HAART programs have started recently and attrition is a major problem.</td>
</tr>
<tr>
<td><strong>EQUITY</strong></td>
<td></td>
</tr>
<tr>
<td>➤ The included studies did not address equity issues.</td>
<td>➤ There might be differential effects of behavioral interventions on HAART adherence according to gender, education, religion, socioeconomic status, and racial or ethnic factors.</td>
</tr>
<tr>
<td><strong>ECONOMIC CONSIDERATIONS</strong></td>
<td></td>
</tr>
<tr>
<td>➤ None of the included studies assessed costs associated with behavioral interventions for improving adherence to HAART.</td>
<td>➤ Effective treatment of HIV is highly cost-effective. However, some behavioral interventions may be very expensive, especially when substantial human resources are required. This may pose a burden in low-income countries in addition to the already costly provision of HAART.</td>
</tr>
<tr>
<td><strong>MONITORING &amp; EVALUATION</strong></td>
<td></td>
</tr>
<tr>
<td>➤ Adherence was measured by self-report or other unreliable methods in some studies.</td>
<td>➤ Measuring adherence is a complex task and frequently used methods such as self-report may lack both sensitivity and specificity. Future studies should use objective measures to provide a more accurate measure of true adherence, although these are more expensive. ➤ Future research should investigate which components of behavioral interventions improve adherence. ➤ Interventions to increase adherence consume resources and attempts to increase adherence can have adverse effects, such as loss of privacy and autonomy, and increased adverse effects of treatments. Adverse effects and costs should be monitored, as well as adherence.</td>
</tr>
<tr>
<td>➤ This review was not able to determine which components of combined interventions are the ones that increase adherence.</td>
<td></td>
</tr>
<tr>
<td>➤ There was little information about costs and adverse effects in the included studies.</td>
<td></td>

About the certainty of the evidence (GRADE)
The “certainty of the evidence” is an assessment of how good an indication the research provides of the likely effect; i.e. the likelihood that the effect will be substantially different from what the research found. By “substantially different” we mean a large enough difference that it might affect a decision. These judgements are made using the GRADE system, and are provided for each outcome. The judgements are based on the study design (randomised trials versus observational studies), factors that reduce the certainty (risk of bias, inconsistency, indirectness, imprecision, and publication bias) and factors that increase the certainty (a large effect, a dose response relationship, and plausible confounding). For each outcome, the certainty of the evidence is rated as high, moderate, low or very low using the definitions on page 3.
